The BOTIK Telecommunication System, Pereslavl-Zalessky

BOTIK provides enterprises, organizations, and private persons with permanent high-speed network connections (100 Mbps backbone, 10–100 Mbps at subscribers) at a reasonable price. Since 2000, the BOTIK telecommunication system has been developing at an exponential rate: all major quantitative indices — number of connections, volume of data transferred, etc — have increased by 1.5 times every year.

BOTIK has more than 800 subscribers — more than 100 organizations and 700 private persons — and over 2,500 networked computers in a town of 45,000 inhabitants. The system covers an area of 6×12 miles. BOTIK provides practically all the town's educational and research institutions, libraries, some medical institutions, town administration, most enterprises, and hundreds of inhabitants with LAN connection: 85% of the subscribers have permanent high-speed connections: Ethernet, 10–100 Mbps).

BOTIK technical solutions for building cost-effective urban networks have been implemented in several regions of Russia and CIS countries; specifically, Almaty, Kazakhstan (www.samal.kz); Moscow, Russia (www.urbannet.ru); Ramenskoye district, Moscow, Russia (www.aviel.ru), and others.

The BOTIK Technologies

Software suite for urban computer networks: NAdmin (administration and billing), BMS (monitoring), BotikMap (specialized GIS), BotikTools (subscribers' software package), IP-telephony support, and other services.

Solutions for copper backbone cables: up to 0.6 miles, 10–100 Mbps, \$0.18–0.25/m.

Fiber-optic switch module (100 Mbps) endures the poor quality of power supply in Russian regions (fluctuation in voltage and irregular power supply).

Hardware for new generation PC Routers: low electricity consumption (about 10–15 W); absence of mechanical moving elements — processor and power unit fans; classic HDD is replaced by 128 MB FLASH memory; the use of power supply unit (with accumulator) produced by the Botik Lab. which supports PC Router operation when external power supply is lacking; microcontroller-based watchdog timers designed by the Botik Lab.

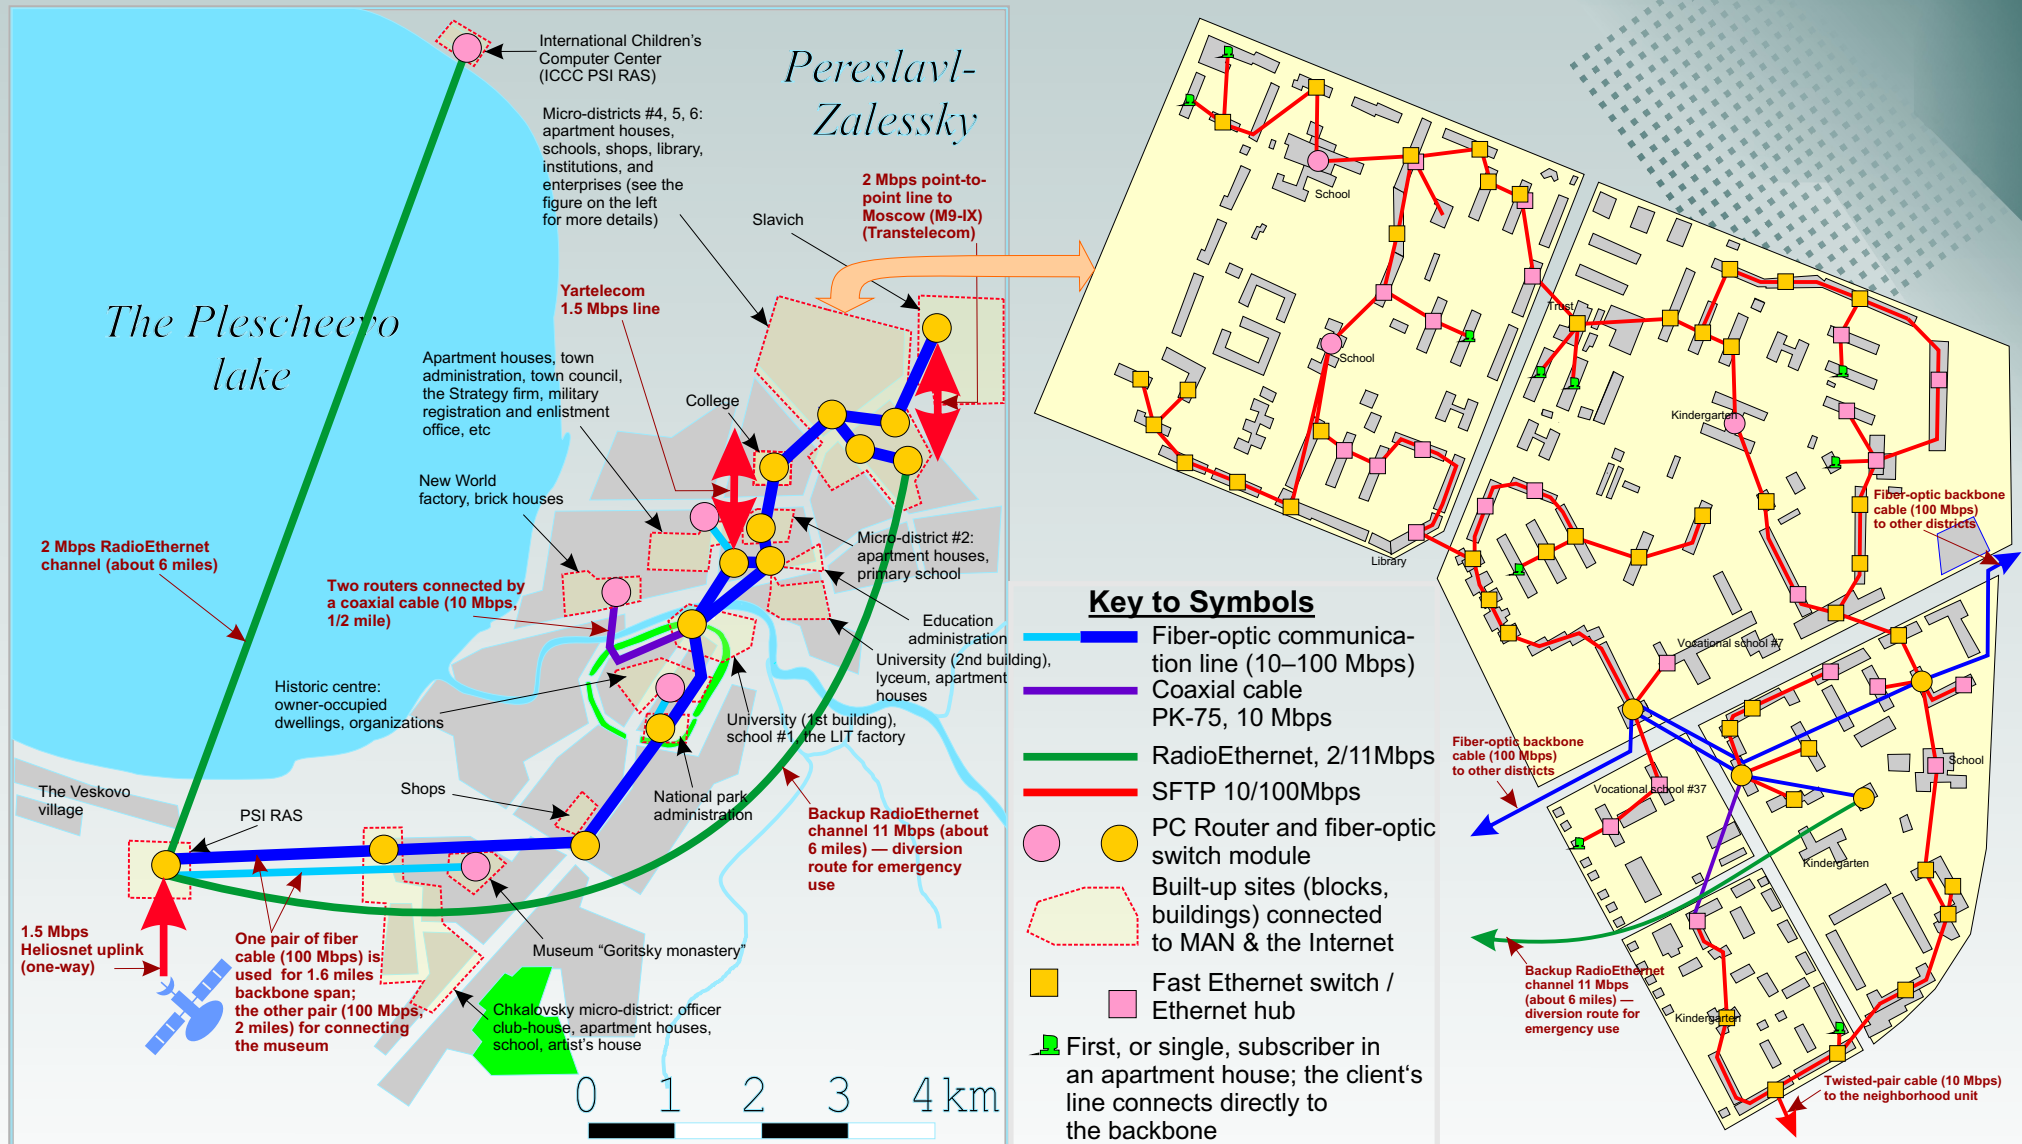

EtherBox: unmanaged switch control module. In order to cut down on network exploitation expenses, it is necessary to automate the monitoring of components' operation to the maximum no matter whether or not the initial device had a control interface. We solved this problem by designing and putting into production a space saving (25×28×10 mm) EtherBox device based on the Atmel chip with an Ethernet port. The device supports TCP/IP and a multicast-based control protocol protected with symmetric cryptography. Attaching this device to a free port of an unmanaged switch makes possible the monitoring of the network node by means of a ping-test.

EtherBox may also be used to connect external devices, sensors, or actuating mechanisms to the network, which makes it possible to monitor and control switches.
